

ALLOCATION MONITOR

TRAINING 2024-12-11 TO 2025-12-10 // CONDITIONAL MODEL ESTIMATES

ALLOLABS

GLOBAL PORTFOLIO RESEARCH

CONSTRUCTION SNAPSHOT

MODEL DISCIPLINE

Returns shown here are optimizer inputs. They combine sample-sensitive estimates and research views; they are not promises of realized performance. Use the report to compare construction and risk, then stress-test assumptions.

HOW TO READ THESE NUMBERS

Historical is descriptive, not predictive.

A strong training period can annualize to an implausibly high number. It records the sample; it does not imply repetition.

The posterior is an optimization input.

Black-Litterman can regularize assumptions, but outputs remain sensitive to priors, covariance, confidence, and the selected universe.

Risk is conditional too.

Volatility and correlation estimates may fail during regime shifts, liquidity shocks, and crowded unwinds.

MODEL NOTES & RISK CONTROLS

WHAT THE SYSTEM ESTIMATES // WHAT IT DOES NOT KNOW

01 RETURN ESTIMATION

With Black-Litterman enabled, an equilibrium prior is blended with security views. Without it, annualized historical returns may be used directly. Neither mode produces a promised outcome.

02 WHY LARGE NUMBERS APPEAR

Short or unusually strong samples can create extreme annualized observations. Concentration can magnify high inputs. Figures above roughly 25% warrant sensitivity testing.

03 RISK MODEL

Volatility and correlations are estimated from the selected window and may understate risk during regime changes or liquidity stress.

04 AI RESEARCH LAYER

AI views summarize supplied evidence. Confidence reflects evidence quality, not the probability of a gain. Every claim requires independent verification.

05 IMPLEMENTATION GAP

Taxes, spreads, market impact, financing, borrow availability, and mandate constraints can materially reduce realized results.
